## Advanced Course <br> Distributed Systems

## Consensus <br> "The Paxos Protocol"

 $+$
## Course Topics

- Intro to Distributed Systems
- Basic Abstractions and Failure Detectors
- Reliable and Causal Order Broadcast
- Distributed Shared Memory
- Consensus (Paxos, Raft, etc.)
- Replicated State Machines + Virtual Logs
- Time Abstractions and Interval Clocks (Spanner etc.)
- Consistent Snapshotting (Stream Data Management)
- Distributed ACID Transactions (Cloud DBs)

## Consensus

- In consensus, the processes propose values
- they all have to agree on one of these values
- Solving consensus is key to solving many problems in distributed computing
- Total order broadcast (aka Atomic broadcast)
- Atomic commit (databases)
- Terminating reliable broadcast
- Dynamic group membership
- Stronger shared store models

## CONSENSUS INTERFACE

## Events

Request：〈c Propose｜v〉
Indication：$\langle\mathrm{c}$ Decide｜v〉

## Properties：

C1，C2，C3，C4

## Single Value Consensus Properties

## C1. Validity

Any value decided is a value proposed

## C2. Agreement

No two correct nodes decide differently

## C3. Termination

Every correct node eventually decides

## C4. Integrity

A node decides at most once

## SAMPLE EXECUTION

Does it satisfy consensus? yes

## Fail-Stop Model Algorithm

- Hierarchical Consensus
- Rely on P + BEB
- Round per process p1, ...pn. Pi is leader of round i.
- Each leader broadcasts and decides value
- First correct process commits the decided value.
- Each future leader adopts that value.

## Single Value Uniform Consensus

- Validity
- Only proposed values may be decided
- Uniform Agreement
- No two processes decide different values
- Integrity
- Each processes can decide a value at most once
- Termination
- Every process eventually decides a value

## SAMPLE EXECUTION

Does it satisfy uniform consensus? no

## Single Value Uniform Consensus

- Solvable in Fail-Stop model (decide on last round) with strong FD
- Not solvable in the Fail-Silent model (asynchronous system model)
- Given a fixed set of deterministic processes there is no algorithm that solves consensus in the asynchronous model if one process may crash and stop
- There are some infinite executions that where processes are not able to decide on a single value
- Fischer, Lynch and Patterson FLP result

## ASSUMPTIONS

- Partially synchronous system
- Fail-noisy model
- Message duplication, loss, re-ordering

## ImPortance

- Paxos is arguably the most important algorithm in distributed computing
- This presentation follows the paper "Paxos Made Simple" (Lamport, 2001)

## High Level View of Paxos

- Elect a single proposer using $\Omega$
- Proposer imposes its proposal to everyone
- Everyone decides
- Problem with $\Omega$
- Several processes might initially be proposers (contention)

## High Level View of Paxos

- Abortable Consensus (Paxos) saves the day
- Processes attempt to impose their proposals
- Might abort if there is contention (safety) (multiple proposers)
- $\Omega$ ensures eventually 1 proposer succeeds (liveness)

## Typical Usage

## Paxos

Ensures correctness (safety)
@
Ensures termination (liveness)
(Leader ~ Paxos Proposer)

The Paxos Algorithm

## TERMINOLOGY

- Proposers
- Will attempt imposing their proposal to set of acceptors
- Acceptors
- May accept values issued by proposers
- Learners
- Will decide depending on acceptors acceptances
- Each process plays all 3 roles in classic setting

## STRAWMAN'S SOLUTION

- Centralized solution
- Proposer sends value to a central acceptor
- Acceptor decides first value it gets
- Problem
- Acceptor is a single-point of failure

## Abortable Consensus

- Decentralises acceptors, i.e. proposers talks to set of acceptors
- Tolerate failures, i.e. acceptors might fail (needs only a majority of acceptors surviving)
- Proposers might fail to impose their proposals (aborts)

## DECENTRALIZATION \& FAULT-TOLERANCE

- Quorum approach
- Each proposer tries to impose its value v on the set of acceptors
- If majority of acceptors accept v , then v is chosen
- Learners try to decide the chosen value

## BALLOT (ROUND) ARRAY (TABLE)

- Describes the state of the acceptors at various rounds
- Each row describes one round
- Each acceptor's state of $\mathrm{a}_{\mathrm{i}}$ initially $\perp$

| Round | $a_{1}$ | $a_{2}$ | $a_{3}$ |
| :--- | :--- | :--- | :--- |
| $n=5$ |  |  |  |
| $\ldots$ |  |  |  |
| $n=2$ |  |  |  |
| $n=1$ |  | $\perp$ | $\perp$ |
| $n=0$ | $\perp$ |  |  |

## WHEN TO ACCEPT

- Ideally, there will be a single proposer
- Should at least provide obstruction-free progress
- Obstruction-free = if a single proposer executes without interference (contention) it makes progress
- Suggested invariant
- P1. An acceptor accepts first proposal it receives

## ATTEMPT

- P1. An acceptor accepts first proposal it receives
- Problem
- Impossible to later tell what was chosen
- Forced to allow restarting! Let acceptors change their minds!

## BALLOT (ROUND) ARRAY (TABLE)

Two proposers p1 and p2 that propose red and blue But $\mathrm{a}_{3}$ crashes

| Round | $a_{1}$ | $a_{2}$ | $a_{3}$ | $a_{4}$ | $a_{4}$ |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $n=5$ |  |  |  |  |  |
| $\ldots$ |  |  |  |  |  |
| $n=2$ |  |  |  |  |  |
| $n=1$ | red | red | red | blue | blue |
| $n=0$ | $\perp$ |  |  | $\perp$ | $\perp$ |

## BALLOT (ROUND) ARRAY (TABLE)

Two proposers p1 and p2 that propose red and blue But $a_{3}$ crashes

| Round | $a_{1}$ | $a_{2}$ | $a_{3}$ | $a_{4}$ | $a_{4}$ |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $n=5$ |  |  |  |  |  |
| $\ldots$ |  |  |  |  |  |
| $n=2$ |  |  |  | blue | blue |
| $n=1$ | red | red | $\perp$ | $\perp$ | $\perp$ |
| $n=0$ | $\perp$ |  |  |  |  |

## Enabling Restarting

- Proposer can try to propose again
- Distinguish proposals with unique sequence number
- Often called ballot number
- Monotonically increasing
- Implementation with n nodes
- process 1 uses seq: $1, n+1,2 n+1,3 n+1, \ldots$
- process 2 uses seq: $2, n+2,2 n+2,3 n+2, \ldots$
- process 3 uses seq: $3, n+3,2 n+3,3 n+3, \ldots$
- or...
- Pair of values: (local clock or logical clock, local identifier)
- Lexicographic order: if clock collides, choose highest pid

## PROBLEM WITH RESTART

## Ballot (round) Array (table)

p1 proposes ( 1, red) and p2 proposes ( 3 , blue) But $\mathrm{a}_{1}$ and $\mathrm{a}_{2}$ crashed

| Round | $a_{1}$ | $\mathbf{a}_{2}$ | $\mathbf{a}_{3}$ | $\mathbf{a}_{4}$ | $\mathbf{a}_{4}$ |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathrm{n}=5$ |  |  |  |  |  |
| $\mathrm{n}=4$ |  |  |  |  |  |
| $\mathrm{n}=3$ |  |  | blue | blue | blue |
| $\mathrm{n}=2$ | red | red | red | $\perp$ | $\perp$ |
| $\mathrm{n}=1$ | red | red | red | $\perp$ | $\perp$ |
| $\mathrm{n}=0$ | $\perp$ |  |  | $\perp$ | $\perp$ |

## Ensuring Agreement

- Problem (previous slide):
- If restarting allowed,
- Majority may first accept red
- Majority may later accept blue
- Solve it by enforcing:
- P2. If proposal ( $\mathrm{n}, \mathrm{v}$ ) is chosen, every higher numbered proposal chosen has value $v$

## BIRDS-EYE VIEW

- Abortable Consensus in a nutshell
- P1. An acceptor accepts first proposal it receives
- P2. If v is chosen, every higher proposal chosen has value v
- Handwaving
- P1 ensures obstruction-free progress and validity
- P2 ensures agreement
- Integrity trivial to implement
- Remember if chosen before, at most choose once

## ATTEMPT

P2. If $v$ is chosen, every higher proposal chosen has value $v$ How to implement it?
P2a. If $v$ is chosen, every higher proposal accepted has value $v$
Lemma

$$
\mathrm{P} 2 \mathrm{a}=>\mathrm{P} 2
$$

## Problem

## Recall

P1. An acceptor accepts first proposal it receives
P2a. If $v$ is chosen, every higher proposal accepted has value $v$
Problem: we cannot prevent an acceptor from accepting higher value proposal

## Solution

Strengthen P2a
P2b. If v is chosen, every higher proposal issued has value v
If obeyed, solves problem
Not allowed anymore.

## BALLOT (ROUND) ARRAY (TABLE)

p 1 proposes (1,red) and p2 proposes (3, blue)
But $\mathrm{a}_{1}$ and $\mathrm{a}_{2}$ crashed before p2 proposes (3, blue)

| Round | $a_{1}$ | $a_{2}$ | $a_{3}$ | $a_{4}$ | $a_{4}$ |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $n=5$ |  |  |  |  |  |
| $n=4$ |  |  |  |  |  |
| $n=3$ |  |  | red | $\perp$ | $\perp$ |
| $n=2$ | red | red | red | $\perp$ | $\perp$ |
| $n=1$ | red | red | red | $\perp$ | $\perp$ |
| $n=0$ | $\perp$ |  |  | $\perp$ | $\perp$ |

## BALLOT (ROUND) ARRAY (TABLE)

p 1 proposes (1,red) and p2 proposes (3, blue)
At round 3 p 2 has to issue $(3, \mathrm{red})$

| Round | $\mathbf{a}_{1}$ | $a_{2}$ | $\mathbf{a}_{3}$ | $\mathbf{a}_{4}$ | $\mathbf{a}_{4}$ |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathrm{n}=5$ |  |  |  |  |  |
| $\mathrm{n}=4$ |  |  |  |  |  |
| $\mathrm{n}=3$ |  |  | red | red | red |
| $\mathrm{n}=2$ | red | red | red | $\perp$ | $\perp$ |
| $\mathrm{n}=1$ | red | red | red | $\perp$ | $\perp$ |
| $\mathrm{n}=0$ | $\perp$ |  |  | $\perp$ | $\perp$ |

## P2 PRESERVED

- P2. If v is chosen, every higher proposal chosen has value v
- P2a. If $v$ is chosen, every higher proposal accepted has value $v$
- P2b. If v is chosen, every higher proposal issued has value v
- Lemma
- P2b $=>$ P2a
- Recall P2a => P2.
- Thus P2b => P2

## Main Lemma

- P2c. If any proposal ( $\mathrm{n}, \mathrm{v}$ ) is issued, there is a majority set S of acceptors such that either
- (a) no one in $S$ has accepted any proposal numbered less than $n$
- (b) $v$ is the value of the highest proposal among all proposals less than n accepted by acceptors in S
- Lemma: P2c => P2b

## CASE A

(a) no one in S has accepted any proposal number < 3 p2 issues (3, blue) at round 3

| Round | $a_{1}$ | $a_{2}$ | $a_{3}$ | $a_{4}$ | $a_{4}$ |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $n=5$ |  |  |  |  |  |
| $n=4$ |  |  |  |  |  |
| $n=3$ | red | red | blue | blue | blue |
| $n=2$ | red | red | $\perp$ | $\perp$ | $\perp$ |
| $n=1$ | red | red | $\perp$ | $\perp$ | $\perp$ |
| $n=0$ | $\perp$ | $\perp$ | $\perp$ | $\perp$ | $\perp$ |

## Case B

- (b) v is the value of the highest proposal among all proposals less than n accepted by acceptors in S
- red is chosen at round 3 , no proposer at round 4
- Proposer at round 5 will always get red querying any majority

| Round | $a_{1}$ | $a_{2}$ | $a_{3}$ | $a_{4}$ | $a_{4}$ |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathrm{n}=5$ |  |  |  |  |  |
| $\mathrm{n}=4$ |  |  |  |  |  |
| $\mathrm{n}=3$ | red | red | red | $?$ | $?$ |
| $\mathrm{n}=2$ | red | red | $?$ | $?$ | $?$ |
| $\mathrm{n}=1$ | red | red | $\perp$ | $\perp$ | $\perp$ |
| $\mathrm{n}=0$ | $\perp$ | $\perp$ | $\perp$ | $\perp$ | $\perp$ |

## Case B

- (b) v is the value of the highest proposal among all proposals less than n accepted by acceptors in S
- red is chosen at round 3 , no proposer at round 4
- Proposer at round 5 will always get red querying any majority

| Round | $a_{1}$ | $a_{2}$ | $a_{3}$ | $a_{4}$ | $a_{4}$ |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathrm{n}=5$ |  | red | red | red |  |
| $\mathrm{n}=4$ |  |  |  |  |  |
| $\mathrm{n}=3$ | red | red | red | $?$ | $?$ |
| $\mathrm{n}=2$ | red | red | $?$ | ? | ? |
| $\mathrm{n}=1$ | red | red | $\perp$ | $\perp$ | $?$ |
| $\mathrm{n}=0$ | $\perp$ | $\perp$ | $\perp$ | $\perp$ | $\perp$ |

## How To Implement P2C

- A proposer at round $\mathbf{n}$ needs a query phase to get

1. the value of highest round number
2. a promise that the state of $S$ does not change until round $\mathbf{n}$

| Round | $a_{1}$ | $a_{2}$ | $a_{3}$ | $a_{4}$ | $a_{4}$ |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $n=5$ |  |  |  |  |  |
| $n=4$ |  |  |  |  |  |
| $n=3$ | red | red | ra |  |  |
| $n=2$ | red | red | $?$ | $\perp$ | $?$ |
| $n=1$ | red | red | $\perp$ | $\perp$ | $\perp$ |
| $n=0$ | $\perp$ |  | $\perp$ | $\perp$ |  |

## Prepare Phase

- A proposer issues prop(n, v)
- Guarantee (P2c)?
- $v$ is the value of the highest proposal among all proposals less than n accepted by acceptors in S
- Need a prepare(n) phase before issuing prop(n, v)
- Extract a promise from a majority of acceptors not to accept a proposal less than $n$
- Acceptor sends back its highest numbered accepted value

## Abortable Consensus in Paxos

## Proposer

Pick unique sequence $n$, send prepare( $n$ ) to all acceptors
3) Proposer upon majority $S$ of promises:

Pick value $v$ of highest proposal number in $S$, or if none available pick $v$ freely Issue accept( $\mathrm{n}, \mathrm{v}$ ) to all acceptors
5) Proposer upon majority $S$ of responses:

If got majority of acks
decide(v) and broadcast decide(v);
Otherwise abort

## Acceptors

2) Upon prepare(n):

- Promise not accepting proposals numbered less than $n$
- Send highest numbered proposal accepted with number less than $n$ (promise)

5) Upon accept( $\mathrm{n}, \mathrm{v}$ ):

- If not responded to prepare $m>n$, accept proposal (ack); otherwise reject (nack)

## abortable consensus satisfies:

P2c. If $(n, v)$ is issued, there is a majority of acceptors $S$ such that:
a) no one in $S$ has accepted any proposal numbered " $<$ " $n$, OR
b) $v$ is value of highest proposal among all proposals "<" $n$ accepted by acceptors in S

KTH-2022

## Getting Familiar with Paxos

## MESSAGE LOSS AND FAILURES

- Many sources of abort
- Contention (multiple proposals competing)
- Message loss (e.g. not getting an ack)
- Process failure (e.g. proposer dies)
- So Proposers try Abortable Consensus again...
- Prepare(5), Accept(5,v), prepare(15), ...
- Eventually the Paxos should terminate (FLP85?)

## FLP GHOST

$p_{1} \quad$ a.prep(1):ok $\quad$ b.prep(3):ok a.acpt(1,v):fail a.prep(4):ok b.acpt(3,v):fail
$p_{2} \quad$ a.prep(1):ok b.prep(3):ok a.acpt(1,v):fail a.prep(4):ok b.acpt(3,v):fail
a.prep(1):ok b.prep(3):ok a.acpt(1,v):fail a.prep(4):ok b.acpt(3,v):fail

## proposers $a$ and $b$ forever racing...

Eventual leader election ( $\Omega$ ) ensures liveness
Eventually only one proposer => termination

## FAMILIARIZING WITH PAXOS (1/4)

Different processes accept different values, same process accepts different values
Assume 4 proposers $\{\mathrm{a}, \mathrm{b}, \mathrm{c}, \mathrm{d}\}, 7$ acceptors $\left\{\mathrm{p}_{1}, \ldots, \mathrm{p}_{7}\right\}$

Optimizations

## PAXOS (AC) IN A NUTSHELL

- Necessary
- Reject accept( $\mathrm{n}, \mathrm{v}$ ) if answered prepare $(\mathrm{m}): m>n$
- i.e. prepare extracts promise to reject lower accept

## Possible scenario \#1

## Caveat

- Proposers $\{\mathrm{a}, \mathrm{b}, \mathrm{c}\}$, acceptors $\left\{\mathrm{p}_{1}, \mathrm{p}_{2}, \mathrm{p}_{3}\right\}$

|  | a.prep(80):ok | b.prep(10):ok | b.accept(10,red):fail |
| :--- | :--- | :--- | :--- |
|   b.prep(10):ok <br> $\mathrm{p}_{2}$ a.prep(80):ok b.accept(10,red):fail <br> $\mathrm{p}_{3}$ a.prep(80):ok b.prep(10):ok | b.accept(10,red):fail |  |  |
|  |  |  |  |

- accept(10) will be rejected, why answer prepare(10)?
- No point answering prepare( n ) if accept $(\mathrm{n}, \mathrm{v})$ will be rejected

## SUMMARY OF OpTIMIZATIONS

- Necessary
- Reject accept(n,v) if answered prepare(m) :m>n
- i.e. prepare extracts promise to reject lower accept
- Optimizations
- a) Reject prepare( n ) if answered prepare(m):m>n
- i.e. prepare extracts promise to reject lower prepare

## Possible scenario \#2

## accept(80,blue) can anyway not get majority, as P2b guarantees every higher proposal issued would have same value!

a.prep(80):ok b.prep(90):ok b.acpt(90,red:):ok a.acpt(80,blue):fail
b.acpt(90,red):ok a.acpt(80,blue):ok
$p_{6}$
b.acpt(90,red):ok a.acpt(80,blue):ok
b.acpt(90,red):ok a.acpt(80,blue):ok

## SUMMARY OF OpTIMIZATIONS (2)

- Necessary
- Reject accept(n,v) if answered prepare(m) : m>n
- i.e. prepare extracts promise to reject lower accept
- Optimizations
a) Reject prepare(n) if answered prepare( $m$ ): $m>n$ i.e. prepare extracts promise to reject lower prepare
b) Reject $\operatorname{accept}(\mathrm{n}, \mathrm{v})$ if answered $\operatorname{accept}(\mathrm{m}, \mathrm{u}): m>n$ i.e. accept extracts promise to reject lower accept
c) Reject prepare(n) if answered $\operatorname{accept}(m, u): m>n$ i.e. accept extracts promise to reject lower prepare

## Possible scenario \#3

## Caveat

## SUMMARY OF Optimizations (3)

- Necessary
- Reject accept(n,v) if answered prepare(m) : m>n
i.e. prepare extracts promise to reject lower accept
- Optimizations
a) Reject prepare(n) if answered prepare(m): $m>n$ i.e. prepare extracts promise to reject lower prepare
b) Reject $\operatorname{accept}(\mathrm{n}, \mathrm{v})$ if answered $\operatorname{accept}(\mathrm{m}, \mathrm{u}): m>n$ i.e. accept extracts promise to reject lower accept
c) Reject prepare( $n$ ) if answered $\operatorname{accept}(m, u): m>n$
i.e. accept extracts promise to reject lower prepare
d) Ignore old messages to proposals that got majority

## State to Remember

- Each acceptor remembers
- Highest proposal (n,v) accepted
- Needed when proposers ask prepare(m)
- Lower prepares anyway ignored (optimization a \& c)
- Highest prepare it has promised
- It has promised to ignore accept(m) with lower number
- Can be saved to stable storage (recovery)

## Omitting Accept

- Paxos requires 2 round-trips (with no contention)
- Prepare(n) : prepare phase (read phase)
- Accept(n, v): accept phase (write phase)
- P2. If v is chosen, every higher proposal chosen has value v
- Improvement
- Proposer skips the accept phase if a majority of acceptors return the same value $v$

## PERFORMANCE

- Paxos requires 4 messages delays (2 round-trips)
- Prepare( n ) needs 2 delays (Broadcast \& Get Majority)
- Accept( $\mathrm{n}, \mathrm{v}$ ) needs 2 delays (Broadcast \& Get Majority)
- In many cases only accept phase is run
- Paxos only needs 2 delays to terminate
- (Believed to be) optimal

Paxos Correctness

P2b. If v is chosen, every higher proposal issued has value v
P2c. If any prop ( $\mathrm{n}, \mathrm{v}$ ) is issued, there is a set S of a majority of acceptors s.t. either
(a) no one in S has accepted any proposal numbered less than n
(b) v is the value of the highest proposal among all proposals less than n accepted by acceptors in S

Lemma: P2c => P2b

## Proof map:

Prove lemma by assuming P2c, prove P2b follows
Prove P2b follows by assuming $v$ is chosen, prove every higher proposal issued has value $v$

Thus: if P2c is true, and prop ( $\mathrm{n}, \mathrm{v}$ ) chosen
Show by induction every higher proposal issued has value v

- P2b. If $v$ is chosen, every higher proposal issued has value $v$
- P2c. If any prop ( $\mathrm{n}, \mathrm{v}$ ) is issued, there is a set $S$ of a majority of acceptors s.t. either
- (a) no one in $S$ has accepted any proposal numbered less than $n$
- (b) $v$ is the value of the highest proposal among all proposals less than $n$ accepted by acceptors in $S$

## Thus: P2c is true, and prop ( $\mathrm{n}, \mathrm{v}$ ) chosen

 Show by induction on (on prop number) every higher proposal issued has value $v$Need to show by induction that all proposals ( $\mathrm{m}, \mathrm{u}$ ), where $\mathrm{m} \geq \mathrm{n}$, have value $\mathrm{u}=\mathrm{v}$

| Round | $a_{1}$ | $a_{2}$ | $a_{3}$ |
| :--- | :--- | :--- | :--- |
| 5 |  |  |  |
| 4 |  |  |  |
| 3 |  |  |  |
| 2 | V | V |  |
| 1 | W | $\perp$ | $\perp$ |
| 0 | $\perp$ | $\perp$ | $\perp$ |

- P2b. If $v$ is chosen, every higher proposal issued has value $v$
- P2c. If any prop $(n, v)$ is issued, there is a set $S$ of a majority of acceptors s.t. either
- (a) no one in $S$ has accepted any proposal numbered less than $n$
- (b) $v$ is the value of the highest proposal among all proposals less than $n$ accepted by acceptors in S

Thus: P2c is true, and prop ( $\mathrm{n}, \mathrm{v}$ ) chosen Show by induction that all proposals ( $\mathrm{m}, \mathrm{u}$ ), where $m \geq n$, have value $u=v$

## Induction base

Inspect proposal ( $\mathrm{n}, \mathrm{u}$ ).
Since ( $\mathrm{n}, \mathrm{v}$ ) chosen \& proposals are unique, $\mathrm{u}=\mathrm{v}$

| Round | $a_{1}$ | $a_{2}$ | $a_{3}$ |
| :--- | :--- | :--- | :--- |
| 5 |  |  |  |
| 4 |  |  |  |
| 3 |  |  |  |
| 2 | V | V |  |
| 1 | w | $\perp$ | $\perp$ |
| 0 | $\perp$ | $\perp$ | $\perp$ |

## Induction step

- Assume proposals $n, n+1, n+2, \ldots, m$ have value $v$ (ind.hypothesis)
- Show proposal $(\mathrm{m}+1, \mathrm{u})$ has $\mathrm{u}=\mathrm{v}$
- $u$ is the value of the highest proposal among all proposals less than $m+1$ accepted by acceptors in $S$
- By the induction hypothesis, all proposals $n, . . ., m$ have value v . Majority of prop $\mathrm{m}+1$ intersects with majority of prop $n$, thus $u=v$

| Round | $a_{1}$ | $a_{2}$ | $a_{3}$ |
| :--- | :--- | :--- | :--- |
| 5 |  |  |  |
| 4 |  |  | V |
| 3 |  | V |  |

| 0 | $\perp$ | $\perp$ | $\perp$ |

## Agreement Satisfied

This algorithm satisfies P2c

- accept( $\mathrm{n}, \mathrm{v}$ ) only issued if a majority $S$ responded to prepare(n), s.t. for each $p_{i}$ in $S$ :
- a) either: $p_{i}$ hadn't accepted any prop less than $n$, or
-b) $v$ is value of highest proposal less than $n$ accepted by $p_{i}$
- By their promise, a) and b) will not change
- prepare(n) often called read(n)
- $\operatorname{accept}(\mathrm{n}, \mathrm{v})$ often called write( $\mathrm{n}, \mathrm{v}$ )

## Agreement

- P2c. If $(\mathrm{n}, \mathrm{v})$ is issued, there is a majority of acceptors $S$ s.t.
- a) no one in $S$ has accepted any proposal numbered less than $n$, or
- b) v is the value of the highest proposal among all proposals less than n accepted by acceptors in S
- P2. If ( $\mathrm{n}, \mathrm{v}$ ) is chosen, every higher proposal chosen has value v
- We proved that if P 2 c is satisfied, then P 2 is satisfied
- P2c => P2
- Thus the algorithm satisfies agreement (safety)

## Obstruction Freedom and Validity

- P1. An acceptor accepts first "proposal" it receives
- P1 is satisfied because we accept
- if prepare(n) \& accept(n,v) received first
- Thus the algorithm satisfies obstruction-free progress (liveness)
